Community structure in networks

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへで

Community structure in networks

What are communities?

- ► **Traditional definition**: Groups of nodes with a high internal link density
- ► **Modern definition**: Nodes with similar connection probabilities to the rest of the network

▲□▶ ▲圖▶ ▲国▶ ▲国▶ - 国 - のへで

Communities in the real-world networks

Social networks:

- Friend-circles
- Research communities
- Co-workers

World Wide Web:

- ▶ Pages with similar contents
- ▶ Webpages under the same domain (e.g. Wikipedia)

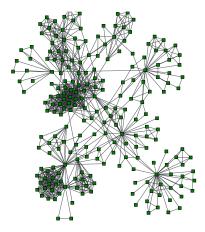

Biological networks:

▶ Proteins with similar roles in protein interaction networks

うして ふゆう ふほう ふほう ふしつ

- Chemicals together taking part in chemical reactions in metabolic networks
- Communities in neuronal networks

Community detection

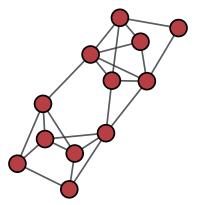

Detecting communities is important!

- Communities are building blocks of networks
- Communities allow us to see "the big picture"
- ▶ Functional/Autonomous units
- Non-trivial effects on the processes on networks

▲□▶ ▲圖▶ ▲国▶ ▲国▶ - 国 - のへで

Graph partitioning

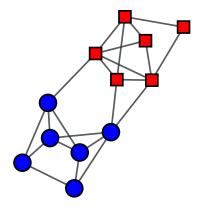

Problem of dividing a graph in a given number of groups of given sizes such that the number of links between the groups (cut size) is minimized

▲□▶ ▲圖▶ ▲国▶ ▲国▶ - 国 - のへで

Graph partitioning

Problem of dividing a graph in a given number of groups of given sizes such that the number of links between the groups (**cut size**) is minimized

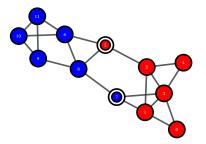

Partitioning is hard!

- Graph with n vertices
- ▶ Find two groups with sizes *n*₁ and *n*₂ such that the cut size is minimum
- Number of ways: $\frac{n!}{n_1!n_2!} \approx \frac{2^{n+1}}{\sqrt{n}}$

Heuristics are needed!

・ロト ・ 日 ・ モ ト ・ モ ・ うへぐ

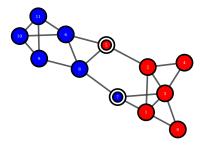

cut size = 4

 Divide the vertices into two groups of the required sizes and calculate the cut size

▲□▶ ▲圖▶ ▲国▶ ▲国▶ - 国 - のへで

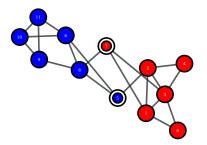

cut size = 4

- Divide the vertices into two groups of the required sizes and calculate the cut size
- Find a pair of nodes which when switched, will reduce the cut size most and switch them

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三回 ● ○○○

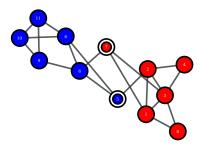

cut size = 2

- Divide the vertices into two groups of the required sizes
- Find a pair of nodes which when switched, will reduce the cut size most and switch them

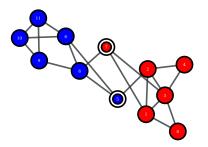

<ロト <回ト < 回ト < 回ト = 三日

cut size = 2

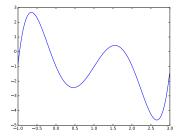

- Divide the vertices into two groups of the required sizes
- Find a pair of nodes which when switched, will reduce the cut size most and switch them
- If no such pair exists, select the pair which least increases the cut size

cut size = 2

- Divide the vertices into two groups of the required sizes
- Find a pair of nodes which when switched, will reduce the cut size most and switch them
- If no such pair exists, select the pair which least increases the cut size
- Continue this such that the already switched pair is not switched again

- Go through all the states and select the one with the least cut size
- Start with this state and repeat the whole procedure
- Continue till the cut size no longer becomes smaller
- Starting with many random initial conditions is better

- ▶ Faster algorithm than Kernighan-Lin
- ▶ Uses properties of the graph Laplacian
- ▶ More complex to implement than Kernighan-Lin

・ロト ・ 日 ・ モ ト ・ モ ・ うへぐ

Cut size:

$$R = \frac{1}{2} \sum_{\substack{i,j \text{ in} \\ \text{different} \\ \text{groups}}} A_{ij}$$

Define

$$s_i = \begin{cases} +1 & \text{if vertex } i \text{ belongs to group 1} \\ -1 & \text{if vertex } i \text{ belongs to group 2} \end{cases}$$

Then

$$\frac{1}{2}(1-s_is_j) = \begin{cases} 1 & \text{if } i \text{ and } j \text{ are in different groups,} \\ 0 & \text{if } i \text{ and } j \text{ are in the same group} \end{cases}$$

$$R = \frac{1}{4} \sum_{ij} A_{ij} (1 - s_i s_j)$$

First term,

$$\sum_{ij} A_{ij} = \sum_{i} k_i = \sum_{i} k_i s_i^2 = \sum_{ij} k_i \delta_{ij} s_i s_j$$
$$R = \frac{1}{4} \sum_{ij} (k_i \delta_{ij} - A_{ij}) s_i s_j = \frac{1}{4} \sum_{ij} L_{ij} s_i s_j$$

$$R = \frac{1}{4} \mathbf{s}^T \mathbf{L} \mathbf{s}$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

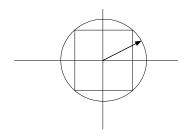

Relaxation method

Two constraints:

• s_i can be only ± 1

$$\blacktriangleright \sum_{i} s_i = n_1 - n_2 \Rightarrow \mathbf{1}^T \mathbf{s} = n_1 - n_2$$

Relax the first constraint

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Minimization with constraints \Rightarrow Lagrange multipliers

$$\frac{\partial}{\partial s_i} \left[\sum_{jk} L_{jk} s_j s_k + \lambda \left(n - \sum_j s_j^2 \right) + 2\mu \left((n_1 - n_2) - \sum_j s_j \right) \right] = 0$$

Minimization with constraints \Rightarrow Lagrange multipliers

$$\frac{\partial}{\partial s_i} \left[\sum_{jk} L_{jk} s_j s_k + \lambda \left(n - \sum_j s_j^2 \right) + 2\mu \left((n_1 - n_2) - \sum_j s_j \right) \right] = 0$$
$$\sum_j L_{ij} s_j = \lambda s_i + \mu$$

Minimization with constraints \Rightarrow Lagrange multipliers

$$\frac{\partial}{\partial s_i} \left[\sum_{jk} L_{jk} s_j s_k + \lambda \left(n - \sum_j s_j^2 \right) + 2\mu \left((n_1 - n_2) - \sum_j s_j \right) \right] = 0$$
$$\sum_j L_{ij} s_j = \lambda s_i + \mu$$
$$\mathbf{Ls} = \lambda \mathbf{s} + \mu \mathbf{1} = \lambda \left(\mathbf{s} + \frac{\mu}{\lambda} \mathbf{1} \right)$$
$$\mathbf{L} \left(\mathbf{s} + \frac{\mu}{\lambda} \mathbf{1} \right) = \lambda \left(\mathbf{s} + \frac{\mu}{\lambda} \mathbf{1} \right)$$

 $\mathbf{1}$ is an eigenvector of the Laplacian with eigenvalue 0

$$\mathbf{L}\mathbf{x} = \lambda \mathbf{x}$$

${\bf x}$ is an eigenvector of the Laplacian with eigenvalue λ

Which eigenvector to choose?

x cannot be the eigenvector
$$\mathbf{1} = \begin{pmatrix} 1\\1\\.\\.\\1 \end{pmatrix}$$

$$\mathbf{1}^T \mathbf{x} = \mathbf{1} \left(\mathbf{s} + \frac{\mu}{\lambda} \mathbf{1} \right) = (n_1 - n_2) + \frac{\mu}{\lambda} n = 0$$

Which eigenvector to choose?

$$R = \frac{1}{4}\mathbf{s}^T \mathbf{L}\mathbf{s} = \frac{1}{4}\mathbf{x}^T \mathbf{x} = \frac{n_1 n_2}{n}\lambda$$

Choose the eigenvector with smallest possible eigenvalue!

Eigenvalues of the Laplacian are non-negative and smallest is always 0

 $\mathbf{v}_1 = \mathbf{1}$ is ruled out already. So choose \mathbf{v}_2 with the smallest positive eigenvalue

・ロト ・ 日 ・ モ ト ・ モ ・ うへぐ

$$\mathbf{s} = x + \frac{n_1 - n_2}{n} \mathbf{1}$$

OR

$$s_i = x_i + \frac{n_1 - n_2}{n}$$

But s_i can be only ± 1

Thus, we want \mathbf{x} to be as close as possible to \mathbf{s}

Maximize:

$$\mathbf{s}^T\left(\mathbf{x} + \frac{n_1 - n_2}{n}\mathbf{1}\right) = \sum_i s_i\left(x_i + \frac{n_1 - n_2}{n}\right)$$

Equivalently, maximize:

$$\sum_{i} s_i x_i$$

Simply put the n_1 vertices with most positive elements in group 1 and the rest ones in group 2

Group assignments are arbitrary

ション ふゆ マ キャット マックシン

- Calculate \mathbf{v}_2 of the Laplacian
- Put vertices corresponding to largest n₁ elements in group
 1 and others in group 2. Calculate the cut size
- ▶ Put vertices corresponding to smallest n₁ elements in group 1 and others in group 2. Calculate the cut size
- Choose the division with the smallest cut size among the two

うして ふゆう ふほう ふほう ふしつ

Community detection is harder!

Graph partitioning

- well defined
- Number of groups is fixed
- Sizes of the groups are fixed
- Divide even if no good division exists

Community detection

- \blacktriangleright ill-defined
- ▶ Number of groups depends on the structure of the network
- ▶ Sizes of the groups depend on the structure of the network

ション ふゆ マ キャット マックシン

Discover natural fault lines

Many definitions.. many algorithms!

- ▶ Girvan-Newman algorithm
- ▶ Kernighan-Lin-Newman algorithm
- Spectral decomposition
- Clique-percolation
- ▶ Radom walk methods
- Statistical inference
- Label propagation
- ▶ Hierarchical clustering

・ロト ・ 日 ・ モ ・ ト ・ モ ・ うへぐ

Broad classification

• Agglomerative algorithms:

- ▶ Hierarchical clustering
- Louvain method
- CNM algorithm
- Divisive algorithms:
 - ▶ Girvan-Newman algorithm
 - Radichhi algorithm

Assignment algorithms:

- Label propagation
- Spectral partitioning
- ▶ Kernighan-Lin-Newman algorithm

◆□ → ◆□ → ▲ □ → ▲ □ → ◆ □ → ◆ ○ ◆

"The" simplest community detection problem

- Bisecting a graph with n nodes
- Group sizes are not fixed
- Minimum cut size?
 - Trivial partition
 - Needs ad hoc specification of sizes

ション ふゆ マ キャット しょう くしゃ

"The" simplest community detection problem

- Bisecting a graph with n nodes
- Group sizes are not fixed
- Minimum cut size?
 - Trivial partition
 - Needs ad hoc specification of sizes

A different measure of the quality of division is required..

ション ふゆ マ キャット しょう くしゃ

▶ Fewer than expected edges between the groups

- ▶ Fewer than expected edges between the groups
- ▶ Equivalently, more than expected edges inside the groups

$$Q = \frac{1}{2m} \sum_{ij} \left(A_{ij} - \frac{k_i k_j}{2m} \right) = \frac{1}{2m} \sum_{ij} B_{ij} \delta(c_i, c_j)$$

Note that:

$$\sum_{j} B_{j} = \sum_{j} A_{ij} - \frac{k_{i}}{2m} \sum_{j} k_{j} = k_{i} - \frac{k_{i}}{2m} 2m = 0$$

$$s_i = \begin{cases} +1 & \text{if vertex } i \text{ belongs to group } 1 \\ -1 & \text{if vertex } i \text{ belongs to group } 2 \end{cases}$$

$$s_i = \begin{cases} +1\\ -1 \end{cases}$$

1

if vertex i belongs to group 1 if vertex i belongs to group 2

$$\frac{1}{2}(1+s_is_j) = \begin{cases} 1\\ 0 \end{cases}$$

if i and j belong to the same group Otherwise

▲□▶ ▲圖▶ ▲国▶ ▲国▶ - 国 - のへで

$$s_i = \begin{cases} +1 & \text{if vertex } i \text{ belongs to group } 1 \\ -1 & \text{if vertex } i \text{ belongs to group } 2 \end{cases}$$

$$\frac{1}{2}(1+s_is_j) = \begin{cases} 1 & \text{if } i \text{ and } j \text{ belong to the same group} \\ 0 & \text{Otherwise} \end{cases}$$

$$B = \frac{1}{2m} \sum_{ij} B_{ij} \delta(c_i, c_j) = \frac{1}{4m} \sum_{ij} B_{ij} (1 + s_i s_j) = \frac{1}{4m} \sum_{ij} B_{ij} s_i s_j$$

$$Q = \frac{1}{4m} \mathbf{s}^T \mathbf{B} \mathbf{s}$$

▲□▶ ▲圖▶ ▲≣▶ ▲≣▶ ■ のへで

Relaxation method

▶ Numbers of elements with values +1 and -1 are not fixed

• Only constraint:
$$\mathbf{s}^T \mathbf{s} = \sum_i s_i^2 = n$$

 $\frac{\partial}{\partial s_i} \left[\sum_{ij} B_{jk} s_j s_k + \beta \left(n - \sum_j s_j^2 \right) \right] = 0$
 $\sum_j B_{ij} s_j = \beta s_i$
 $\mathbf{Bs} = \beta \mathbf{s}$

$$Q = \frac{1}{4m} \beta \mathbf{s}^T \mathbf{B} \mathbf{s} = \frac{1}{4m} \beta \mathbf{s}^T \mathbf{s} = \frac{n}{4m} \beta$$

Thus, choose \mathbf{s} to be the eigenvector \mathbf{u}_1 corresponding to the largest eigenvalue of the modularity matrix Maximize:

$$\mathbf{s}^T \mathbf{u}_1 = \sum_i s_i u_{1i}$$

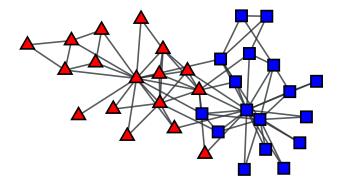

Maximum is achieved when each term is non-negative \Rightarrow Use signs of $u_{1i}!$

Degeneracy

Resolution limit

Structure vs Noise

Degeneracy

Resolution limit

- Maximizing the modularity can fail to resolve small sized modules
- Modular structures like cliques can be hidden in the larger groups of nodes with higher modularity score
- Peak of the modularity function may not coincide with divisions that identify such modular structures

$$Q = \frac{1}{2m} \sum_{ij} \left(A_{ij} - \frac{k_i k_j}{2m} \right) \delta(c_i, c_j)$$

Contribution of the group s,

$$Q_s = \frac{1}{2m} \sum_{ij} \left(A_{ij} - \frac{k_i k_j}{2m} \right) \delta(c_i, s) \delta(c_j, s) = \frac{e_s}{m} - \left(\frac{d_s}{2m} \right)^2$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Resolution limit

The group s is a module whenever $Q_s > 0 \Rightarrow \frac{e_s}{m} > \left(\frac{d_s}{2m}\right)^2$

Consider two modules s_1 and s_2 with $e_{s_1s_2}$ edges between them The change in modularity if we merge these:

$$\triangle Q_{s_1s_2} = \frac{e_{s_1s_2}}{m} - 2\left(\frac{d_{s_1}}{2m}\right)\left(\frac{d_{s_2}}{2m}\right) > 0$$

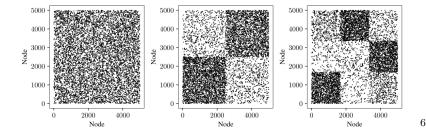

whenever:

$$e_{s_1s_2} > \frac{d_{s_1}d_{s_2}}{2m} \to 0$$

Thus, modules would be merged even when the number of links $e_{s_1s_2}$ between them is small! ⁵

⁵Fortunato, Barthelemy, Resolution limit in community detection, PNAS, (2006)

Structure vs Noise

⁶Tiago Peixoto, Bayesian stochastic blockmodeling $\langle \mathcal{B} \rangle$, $\langle \mathbb{B} \rangle$, $\langle \mathbb{B} \rangle$, \mathbb{B}

Conclusions

- Community structure is a fundamental property of networks
- ▶ Community detection is an ill-defined problem
- ▶ (Too) many algorithms exist
- Community detection is still an open problem!
